Examples of Achievement

Examples of recent achievements of the Indoor Environment Department are listed below.

- Characterized the relationship between rates of outdoor air supply to office buildings and the office worker's health symptoms and work performance
- Quantified the relationship between dampness and mold in homes and prevalence of asthma and respiratory health effects
- Identified the opportunity to simultaneously improve comfort, health, and building energy performance through better control of air temperatures in offices
- Evaluated technologies for measuring and controlling office building ventilation rates, providing guidance for equipment selection
- Developed an improved method for measuring the rates of air leakage in residential duct systems
- Led the development of the first ASHRAE ventilation and indoor air quality standard for homes
- Quantified the emission rates of air pollutants from office equipment
- Evaluated the energy performance of residential air handling systems, leading to changes in fan efficiency specifications in California Title 24 codes and to the development of a new ASHRAE standard on residential air handler cabinet leakage
- Developed extensive technical guidance for the ongoing greening of the U.S. Capital Building Complex
- Used model-based interpretations of biomonitoring data to examine and develop hypotheses about the relative impact of indoor and food-based exposures to pesticides
- Applied the "intake fraction" metric to refine methods for estimating human exposure impacts from (a) indoor pollutants, (b) ambient emissions from transportation fuels, and (c) subsurface leaks from pipes and tanks
- In collaboration with a team of researchers supported by the United Nations Environment Program and the Society for Environmental Toxicology and Chemistry, developed an internationally-harmonized life-cycle-impact model called USEtox

The mission of Berkeley Lab's Environmental Energy Technologies Division is to perform research and development leading to better energy technologies that reduce adverse energy-related environmental impacts. Our work increases the efficiency of energy use, reduces its environmental effects, provides the nation with environmental benefits, and helps developing nations achieve similar goals through technical advice.

Significance of Indoor Environments

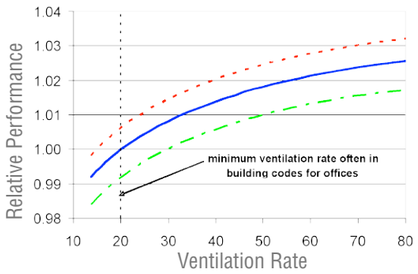
People spend approximately 90 percent of their time indoors. Characteristics of the indoor environment that affect people's comfort, health, and work performance include thermal conditions, concentrations of chemical and biological pollutants, outdoor air supply rates, acoustic conditions, and lighting conditions. Much of the energy use of buildings, such as all of the energy used for heating, ventilating, and air conditioning, is for maintaining acceptable indoor environmental conditions. Many of the changes that can be made to building designs and operational practices to reduce energy consumption will modify aspects of indoor environmental quality with potential impacts, positive or negative, on comfort, health, and performance. Consequently, building energy performance and indoor environmental quality must be addressed in a coordinated manner.

Indoor Environment Department Research Goals

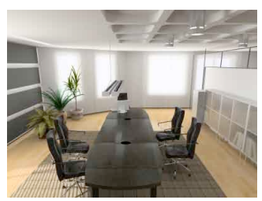
- Reducing the energy used for thermally conditioning and distributing ventilation air in buildings
- Improving indoor air quality (IAQ), thermal comfort and the health and productivity of building occupants
- Improving the scientific understanding of factors and processes affecting indoor air quality, pollutant exposures, and health effects
- Developing the most effective ways of reducing indoor exposures to very hazardous chemical and biological agents in the event of accidental or intentional releases
- Developing input for codes and standards that improve indoor environmental and energy perfor mance of buildings

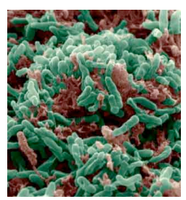
Research Areas

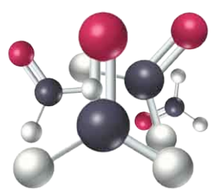
Building Infiltration and Ventilation



Building infiltration and ventilation affects energy consumption, concentrations of indoor air pollutants, and occupant health and performance. Research is conducted to characterize the rates of ventilation in buildings and to elucidate how ventilation affects energy consumption, indoor air quality, health, and performance. Ventilation technologies and control strategies that improve indoor air quality and minimize energy use are evaluated and developed. Models of building ventilation are developed. Input is provided for the development of building ventilation standards and codes.



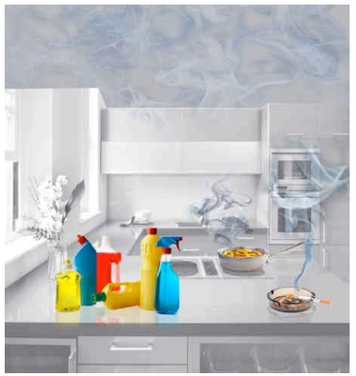




Thermal Distribution

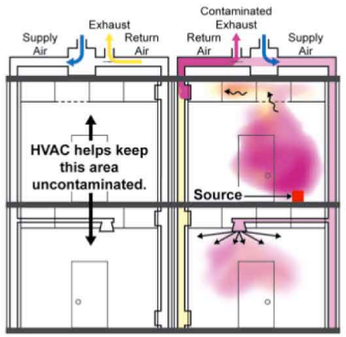
Thermal distribution is the process of moving heat throughout a building for space heating or cooling, such as the movement of heated or cooled air through ducts to maintain thermal comfort. The goal of the Department's thermal distribution research is to ensure that thermal distribution systems operate as intended with minimal energy loss. Research and technology transfer topics include diagnostic methods for evaluating thermal distribution performance in field settings, test procedures for certifying component performance, design guidance for practitioners, and improved thermal distribution technologies. Considerable emphasis is placed on technical contributions to related aspects of codes and standards.

Indoor Pollutants: their Sources, Transport, and Chemical Reactions

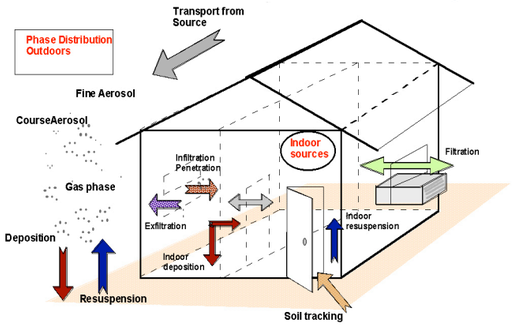


Research is performed to characterize the concentrations of air pollutants in buildings and all of the factors that determine these concentrations. Surveys in populations of buildings establish baseline levels of pollutants and related factors such as outdoor air ventilation rates. Laboratory research quantifies the emission rates of pollutants from various indoor sources. Indoor chemical reactions that transform and create new pollutants are investigated. Indoor air and pollutant transport processes and their impacts on pollutant exposures are evaluated. The transport of pollutants from outdoors to indoors is also investigated. Related measurement techniques are developed or improved. Models are developed and employed to predict pollutant emission rates, transport processes, chemical reactions, pollutant concentrations, and exposures.

Pollutant Exposure Assessment and Modeling



he Department characterizes and models human exposures to a broad range of harmful substances, we conduct research to understand and quantify the emissions, dispersion, and fate of pollutants from indoor and outdoor sources. We work on current and emerging technologies for anticipating and monitoring contaminant exposures for both human and ecological receptors. Current research focuses the physical and chemical processes that govern pollutant concentrations and exposures. We also develop, evaluate, and apply cumulative exposure measurements and models in health-risk assessments. The motivation for this research is to understand and reduce the potential human health and ecological effects of energy, industrial, and agricultural systems.



Energy-efficient technologies and strategies for reducing unacceptable exposures to air pollutants are a major area of emphasis. Related research topics include advances in ventilation system design and operation, pollutant source identification and control measures, particle filtration, gas phase air cleaning, and applications of pollutant sensors. The research scope includes control measures for reducing risks from accidental or intentional indoor or outdoor releases of highly toxic chemical and biological agents.
